How Permutations Displace Points and Stretch Intervals

Daniel Daly

For a permutation $\pi \in S_n$, we define $d(\pi) = \sum_{i=1}^{n} \frac{|i - \pi(i)|}{n}$ which we call the displacement of $\pi$. We consider the questions: for which $\pi$ is $d(\pi)$ maximized and what is the maximum value $d(\pi)$ can take for $\pi \in S_n$? We also consider the normalized displacement $d(\pi)/n$ and compute the expected value of $d(\pi)/n$ as $n$ approaches infinity. Time permitting, we will generalize the question of displacement to the stretching of intervals over the numbers $\{1, \ldots, n\}$ for the specific intervals $\{i, i + 1\}$. This is joint work with Petr Vojtěchovský.
